SNPtools: utilities for SNP data

VJ Carey `stvjc@channing.harvard.edu`

April 13, 2004

Contents

1 Introduction

This document describes `SNPtools` version 1.0, added to Bioconductor in October of 2003. This first version focuses on SNP metadata, with functions that retrieve SNP-related data from the Boston Children's Hospital Informatics Program SNPper web service **?**.

Earlier non-released versions of this package included considerable code for working with prettybase format and for conducting other tasks in SNP discovery projects. That material has been moved to `inst/OLD` and may be re-introduced later. Users seeking legacy support should contact the author.

2 How it works

```
Loading required package: XML
```

The core of this package is the XML-RPC service at CHIP accessible through the following URL stub:

```
> print(.SNPperBaseURL)

[1] "http://snpper.chip.org/bio/rpcserv/dummy?cmd="
```

The `useSNPper` function allows you to work directly with the XML-RPC server by packing up appropriate command and argument strings.

```
> dput(useSNPper)

function (cmd, parmstring)
{
    targ <- url(paste(.SNPperBaseURL, cmd, parmstring, sep = ""))
    open(targ)
    on.exit(close(targ))
    readLines(targ)
}

> print(useSNPper("geneinfo", "&name=CRP")[1:7])

[1] " <SNPPER-RPC SOURCE=\"SNPper - IIPGA - http://snpper.chip.org/\" VERSION=\"$Rev
[2] "  <GENEINFO>"
[3] "    <GENE ID=\"799\">"
[4] "      <GENEID>799</GENEID>"
[5] "      <NAME>CRP</NAME>"
[6] "      <CHROM>chr1</CHROM>"
[7] "      <STRAND>-</STRAND>"
```

The main functions of *SNPtools* attend to simplifying specification of parameters and parsing and packaging the XML results.

Note on auditability. All functions return textual information coupled with auditing information as a 'toolInfo' attribute, detailing the SNPper supplied information on the human genome sequence build, the dbSNP version, and the SNPper version from which the results are obtained. At present, there is one exception: when `itemsInRange` is invoked with `item='countsnps`, no toolInfo data is obtained. This will be corrected once the `countsnps` command at SNPper returns valid XML element tags.

3 Overview of the functions

The current set of functions intended for investigative use is:

- `geneInfo` – general information about location and nomenclature
- `geneLayout` – information about exon locations

- `geneSNPs` – all SNPs associated with a given gene
- `SNPinfo` – detailed information on a SNP
- `itemsInRange` – supports chromosome scanning for genes, SNPs, or counts of SNPs

An omission: for SNP information, I have not collected information on submitter.

4 Demonstrations

4.1 Obtaining information on genes

The `geneInfo` function will collect some basic information on a gene. The gene may be specified by HUGO name, mRNA accession number, or SNPper id.

```
> print(geneInfo("CRP"))
```

```
                                  snpper.ID                                       NAME
                                      "799"                                      "CRP"
                                     CHROM                                     STRAND
                                     "chr1"                                        "-"
                                    PRODUCT                                  LOCUSLINK

4.2 Obtaining information on SNPs

Suppose you want information on the SNP with dbSNP id rs25.

```
> print(SNPinfo("25"))

   DBSNPID      TSCID CHROMOSOME   POSITION    ALLELES       ROLE     RELPOS
    "rs25"        " "     "chr7" "11328479"      "A/G"        " "        " "
     AMINO   AMINOPOS
       " "        " "
attr(,"toolInfo")
                                     SOURCE
"SNPper - IIPGA - http://snpper.chip.org/"
                                    VERSION
                        "$Revision: 1.34 $"
                                     GENOME
                                     "hg16"
                                      DBSNP
                                      "118"
```

Suppose instead you want information on all the SNPs cataloged in a certain chromosomal region.

```
> ird <- itemsInRange("snps", "chr1", "156400000", "156500000")
> print(length(ird))

[1] 160

> print(ird[1:3])
```

```
[[1]]
          DBSNPID              TSCID         CHROMOSOME           POSITION

         AMINOPOS               HUGO          LOCUSLINK               NAME
              " "               "FY"             "2532" "Duffy blood group"
            MRNA
       "NM_002036"

[[2]]
          DBSNPID              TSCID         CHROMOSOME           POSITION
       "rs3027049"                " "             "chr1"        "156401020"
          ALLELES               ROLE             RELPOS              AMINO
            "A/C"              "UTR"             "9004"                " "
         AMINOPOS               HUGO          LOCUSLINK               NAME
              " "               "FY"             "2532" "Duffy blood group"
            MRNA
       "NM_002036"

[[3]]
          DBSNPID              TSCID         CHROMOSOME           POSITION
       "rs3027050"                " "             "chr1"        "156401029"
          ALLELES               ROLE             RELPOS              AMINO
            "C/G"              "UTR"             "9013"                " "
         AMINOPOS               HUGO          LOCUSLINK               NAME
              " "               "FY"             "2532" "Duffy blood group"
            MRNA
       "NM_002036"
```

Note that the start and end locations are supplied as strings. This is to avoid coercion to textual scientific notation.

Additional detail on the count of SNPs can be obtained more briefly:

```
> print(itemsInRange("countsnps", "chr1", "156400000", "156500000"))

 total exonic nonsyn
   156      3      2
```

To see all the SNPs associated with a given gene, use the `geneSNPs` function. This requires knowledge of the SNPper gene id, which can be obtained using `geneInfo`.

```
> gs <- geneSNPs("546")
> print(length(gs))
```

```
[1] 64
```

```
> print(gs[1:3])
```

```

```

5 Application: SNP density on chr 1

Human chromosome 1 is approximately 300Mb, and 142,629 SNPs have been recorded as of dbSNP build 106, according to NCBI SNP/maplists/maplist-newmap.html on 13 Sep 03. Let's see if these facilities can recover this sort of information. Counting the number of SNPs on a long chromosomal region seems to take a long time for SNPper, so we will break up the task.

```
> print(itemsInRange("countsnps", "chr1", "1", "100000"))
```

```
 total exonic nonsyn
   171      0      0

> system("sleep 2")
> print(itemsInRange("countsnps", "chr1", "100001", "200000"))

 total exonic nonsyn
     0      0      0

> system("sleep 2")
> print(itemsInRange("countsnps", "chr1", "200001", "300000"))

 total exonic nonsyn
    13      0      0

> system("sleep 2")
```

These runs complete in a reasonable amount of time. Here we will just look at the first 2Mb in intervals of .1Mb.

```
> starts <- as.character(as.integer(seq(1, 2000001, 1e+05)))
> ends <- as.character(as.integer(as.integer(starts) + 99999))
> out <- matrix(NA, nr = 20, nc = 3)
> for (i in 1:20) {
+     cat(i)
+     out[i, ] <- itemsInRange("countsnps", "chr1", starts[i],
+         ends[i])
+     system("sleep 2")
+ }

12345678910111213141516171819 20

> print(out)
