1. Documentation For Package OW

1.1. Introduction

This package installs OWFS (see chapter 1.3) and provides read/write access to a 1–wire bus plugged to fli4l. A 1–wire busmaster is connected to a serial interface[1] or to a USB port[2] of the PC. In addition, the OPT also supports I^2C adapters and binding to an OWServer. Find more details in the man pages following (chapter: A.6). The 1–wire-side of the adapters is connected to the 1–wire bus.

1.2. Hardware

1.2.1. The 1–Wire Standard

The 1–Wire ® resp. One-Wire bus from Maxim (Maxim/Dallas) describes a serial interface that uses just one data wire and is used both as a power supply and as a transmit and receive line. However, a „return“ (GND) is required. Every 1–Wire chip has a unique ID number by which it can be addressed. So several 1–Wire devices can be connected on a single bus.

1.2.2. The 1–Wire-Components

Maxim offers a variety of 1–Wire-Components: Serial-, USB-, I^2C-adapters, thermometers, switches(up to 8 channels), EEPROMs, Clocks, A/D-converters, digital potentiometer. You really get everything you need for home automation. An overview of the major components can be found in the appendix under A.2. You may also connect iButton ® parts (NV-RAM, EPROM, EEPROM, Temperature, Humidity, RTC, SHA, Logger).

1.2.3. The 1–Wire-Bus

The 1–wire-bus in principle consists of two twisted lines, in accordance with corresponding topologies longer distances up to 150 m should not be a problem. Cat5 twisted pair Ethernet cable is often used for the wiring. For the assignment of the individual cores, different approaches exist. Maxim uses 6-pin modular jacks and plugs (RJ-11) and has created its own standard, but this does not fit the 8-pin RJ-45 plug stuff. Further standards are described in the appendix (chapter A.1). You will also find informations on the topology of the bus at Maxim, their website offers everything you need to deal with 1–wire.

[1] DS9097U COM Port adadpter.

[2] DS9490R USB Bridge also in conjunction with DS1402D-DR8 (Blue Dot™) for iButton. All DS9490 adapters based on DS2490 USB–1–wire-chips.

1.3. OWFS

OWFS stands for „One Wire File System“. This is a software developed by Paul H. Alfille licensed under the GPL. Based on a 1–Wire-protocol system libraries (OWLib) depict the 1–Wire-Bus OWFS as a file system. In addition, the program offers additional implementations, as owserver, owshell, owhttpd, owftpd, owtap and language modules for capi, perl, tcl, php, which were not included in the present adaption for fli4l. Details on OWFS and a lot of interesting things for 1–Wire may be found at: http://owfs.org/ and http://sourceforge.net/projects/owfs/.

1.4. Fuse

Fuse stands for „filesystem in userspace“. Fuse enables the implementation of a fully functional filesystem in userspace. With the installation of OPT_OW the Fuse kernel module is automatically loaded at startup. Everything else about Fuse can be found at: http://fuse.sourceforge.net/ and http://sourceforge.net/projects/fuse/.

1.5. libusb

libusb is a free, GPL-licensed USB library which is required to access the 1–wire bus with a USB adapter. Everything else concerning libusb can be found at: http://libusb.sourceforge.net/

1.6. License

This program is licensed under the GNU General Public License, Version 2, June 1991 and can be freely used, reproduced and altered under the conditions indicated. The text of the GNU General Public License can be found at: http://www.gnu.org/licenses/gpl.txt

1.7. Warranty And Liability Disclaimer

This program was devloped with the will and in the hope that it will be useful. Nevertheless, there is no warranty of any kind – Warranty of merchantability or fitness for a particular purpose are rejected. For details, refer to the GNU General Public License (GPL). There is no liability for loss of data, damage to hardware or software or any other damage.

1.8. System Requirements

based on the size of OPT_OW a harddisk resp. a flash card is needed. For details see OPT_HD.

For display in a browser the webserver from fli4l package „httpd“ is needed. For further details see chapter 1.13.1.

Please note:

The USB control via the W1 kernel modules does not yet work (according to Paul Alfille, the maintainer of OWFS) and has not been tested in Opt. (The W1 modules for version V2.8 p16 and p19 were tested once, but since connection and evaluation are completely different from the standard version, were not examined further for correct funtion)

To use the USB adapter the details of the system must be present in "udev" in "rules.d". Only if these settings are correct, the connection to OWSERVER and OWFS will work.

The use of the two programs *owshell* and *owhttpd* did not work properly on some hardware environments. The authors try to find a solution to the problem in collaboration with Paul Alfille. If errors occur, you may try posting on the fli4l newsgroup with a detailed description of your problem.

1.9. Installation

After unpacking the tar.gz archive into the fli4l directory adapt the file config/ow.txt to your needs. To use the web interface activate the httpd webserver via `OPT_HTTPD`='yes' (see chapter 1.11). If RRDTool is used for recording system readings, the configuration of the text fileconfig/rrdtool.txt is needed too (see chapter 1.15).

1.10. Configuration

Example configuration without comments, further explanations below:

```
OPT_OW='yes'                        # install OPT_OW (yes/no)
OW_USER_SCRIPT=''                   # e.g. 'usr/local/bin/ow-user-script.sh'

OW_OWFS='yes'                       # start owfs (yes/no)
OW_OWFS_DEV='usb'                   # usb*, ttyS*, ip:port, etc.
OW_OWFS_GROUP_N='4'                             # number of groups
OW_OWFS_GROUP_1_NAME='1--Wire at USB'           # name of first group
OW_OWFS_GROUP_1_PORT_N='2'                      # number of ports of device
OW_OWFS_GROUP_1_PORT_1_ID='81.70D42A000000/ID'      # ID of device
OW_OWFS_GROUP_1_PORT_1_ALIAS='ID'                   # alias of ID
OW_OWFS_GROUP_1_PORT_2_ID='81.70D42A000000/Admin/*' # admin-access
OW_OWFS_GROUP_1_PORT_2_ALIAS='Admin/'               # alias of admin

OW_OWFS_GROUP_2_NAME='Heating'
OW_OWFS_GROUP_2_PORT_N='7'
OW_OWFS_GROUP_2_PORT_1_ID='3A.F6E401000000/PA'
OW_OWFS_GROUP_2_PORT_1_ALIAS='1. circulation pump'
OW_OWFS_GROUP_2_PORT_2_ID='3A.F6E401000000/PB'
OW_OWFS_GROUP_2_PORT_2_ALIAS='2. charging pump'
OW_OWFS_GROUP_2_PORT_3_ID='10.651BA9010800/temp'
OW_OWFS_GROUP_2_PORT_3_ALIAS='4. Return temperature'
OW_OWFS_GROUP_2_PORT_4_ID='10.DEF0A8010800/temp'
OW_OWFS_GROUP_2_PORT_4_ALIAS='3. flow temperature'
OW_OWFS_GROUP_2_PORT_5_ID='3A.F6E401000000/Admin/*'
OW_OWFS_GROUP_2_PORT_5_ALIAS='Admin/Switch-'
OW_OWFS_GROUP_2_PORT_6_ID='10.DEF0A8010800/Admin/*'
OW_OWFS_GROUP_2_PORT_6_ALIAS='Admin/VLT-'
OW_OWFS_GROUP_2_PORT_7_ID='10.651BA9010800/Admin/*'
OW_OWFS_GROUP_2_PORT_7_ALIAS='Admin/RLT-'

OW_OWFS_GROUP_3_NAME='Solar devices'
OW_OWFS_GROUP_3_PORT_N='3'
```

```
OW_OWFS_GROUP_3_PORT_1_ID='1C.7F6CF7040000/P0'
OW_OWFS_GROUP_3_PORT_1_ALIAS='1. charging pump'
OW_OWFS_GROUP_3_PORT_2_ID='1C.7F6CF7040000/P1'
OW_OWFS_GROUP_3_PORT_2_ALIAS='2. valve'
OW_OWFS_GROUP_3_PORT_3_ID='1C.7F6CF7040000/Admin/*'
OW_OWFS_GROUP_3_PORT_3_ALIAS='Admin/Switch-'

OW_OWSHELL='yes'
OW_OWSHELL_RUN='yes'
OW_OWSHELL_DEV='usb'
OW_OWSHELL_PORT='127.0.0.1:4304'

OW_OWHTTPD='yes'
OW_OWHTTPD_RUN='yes'
OW_OWHTTPD_DEV='127.0.0.1:4304'
OW_OWHTTPD_PORT='8080'
```

The following variables have to be to configured in the file config/ow.txt:

OPT_OW With the default setting OPT_OW='no', the package is not installed. Using `OPT_OW`='yes' activates the package.

OW_USER_SCRIPT This variable defines the path and file name of an optional background control, with which, for example, the heating system can be controlled. Further details can be found in chapter 1.14.3.

OW_OWFS OWFS provides easy access to the 1–wire bus via the fli4l web interface. By specifying `OW_OWFS`='yes' a file system in the default path '/var/run/ow' is generated using fuse. The 1–wire bus is depicted there. The directories created in the file system are sorted by Identnumbers (see Appendix A.2) of the chips. With the family code of the components a corresponding sortorder can easily be created.

OW_OWFS_DEV The variable `OW_OWFS_DEV` defines the PC interface the 1–wire adapter is connected to.

PC interface	Variable set to	Example
serial	ttyS*	ttyS0 = COM1, ttyS1 = COM2
USB	ttyUSB*	ttyUSB1 = first USB adapter
	usb	usb = first USB adapter
	usb[2-9]	usb3 = third USB adapter
I^2C	i^2c-[0-9]	i^2c-0 = first I^2C port
Simulation	fake	For using '`FAKE`' and '`TESTER`' modes set the variables `OW_OWFS_FAKE` or `OW_OWFS_TESTER` to valid family codes, see chapter 1.11
	tester	

OW_OWFS_GROUP_N The variable `OW_OWFS_GROUP_N` specifies the number of groups displayed in the browser where In- and Outputs belonging together i.e. for driving a solar device and the corresponding names for OW_OWFS_GROUP_NAME are defined.

OW_OWFS_GROUP_x_PORT_N OW_OWFS_GROUP_x_PORT_x_ID OW_OWFS__GROUP_x_
The variable `OW_OWFS_GROUP_x_PORT_N` defines the number of ports for a group. With the

two subsquent variables `OW_OWFS_GROUP_x_PORT_x_ID` and `OW_OWFS_GROUP_x_PORT_x_ALIAS` you assign a name to the In- resp. Output of 1–wire components.

If you want to suppress display of certain data in the web interface, i.e. because the port of a component has not been established or after completion of the configuration the admin branch is no longer needed, you can prefix the name with an exclamation mark (!).

OW_OW_SHELL Activation of the OWFS "server", for providing the OWFS-BUS simultaneously for multiple applications (OWFS and OWHTTPD). For using this no other application may be set to the direct interface of the adapter, but instead must be linked to the server.

OW_OW_SHELL_RUN Should the Server service be started at boot time?

OW_OW_SHELL_DEV The device the server accesses (hardware)

OW_OW_SHELL_PORT IP-address and port the server uses. Only the localhost address 127.0.0.1 makes sense here. As a default port 4304 (OWFS port) should be used for the Server. This address is hardcoded into package RRDTool. If you want to collect values via RRDTool you may not change this setting.

OW_OWHTTPD Activation of OWFS's own web server.

OW_OWHTTPD_RUN Should the web server be started during system boot?

OW_OWHTTPD_READONLY Should write access to the components be allowed in OWFS via the web server?

OW_OWHTTPD_DEV Device, the web server accesses. In conclusion with OW_OWSHELL (Server) also a single device may be accessed here.

OW_OWHTTPD_PORT HTTP port for the web server.

Configuration example:

```
OW_OWFS_GROUP_x_PORT_x_ID='29.57D305000000/P6'
OW_OWFS_GROUP_x_PORT_x_ALIAS='EA-Modul/!P6'        # Signal suppressed
OW_OWFS_GROUP_x_PORT_x_ID='29.57D305000000/Admin/*'
OW_OWFS_GROUP_x_PORT_x_ALIAS='EA-Modul/Admin/!'    # Admin path deactivated
                                                   # completely
```

A detailed description for the configuration of OWFS can be found in the appendix „A.6“ and here: http://owfs.org/index.php?page=owfs.

1.11. Miscellaneous Variables

The following variables can be customized via the file config/ow.txt if needed:

OW_LOG_DESTINATION Target for status and error outputs.

```
0 = mixed (1 and 2)
1 = syslog
2 = stderr
3 = off
```

Default setting is '1'.

OW_LOG_LEVEL The Log level (1-9) determines the amount of status and error outputs, with:

```
1 = silent and 9 = maximum verbosity
```

Default setting is '1'.

OW_TEMP_SCALE The available temperature scales.

```
C = "Celsius"
F = "Fahrenheit"
K = "Kelvin"
R = "Rankine"
```

Default setting is 'C'.

OW_REFRESH_INTERVAL Refresh for fli4l-HTTP in seconds. '0' = no refresh.

Default setting is '10'.

OW_OWFS_FAKE Enables the random simulation of 1–wire components. There may be specified multiple components with family code separated by spaces. The simulated states are purely coincidental. The option can not be activated simultaneously with the 'TESTER' mode.

OW_OWFS_TESTER Enables the systematic simulation of 1–wire components. There may be specified multiple components with family code separated by spaces. The simulated conditions follow realistic values. This option can not be activated simultaneously with the 'FAKE' mode.

OW_OWFS_RUN Specifies whether owfs should be started automatically during the boot of the router. Default value is 'yes', whereas with 'no' the application must be started manually.

OW_OWFS_READONLY Sets with "yes" stated that component states can only be read but not written via owfs.

Default setting is 'no'.

OW_OWFS_PATH Specifies the root directory for the fuse directory structure. The default value is '/var/run/ow'. The selected directory should be situated on the RAMdisk for reasons of system performance!

OW_CACHE_SIZE Is used to set the maximum size of the cache in [bytes] on systems with very little RAM disk.

The default value of '0' removes any limitation.

OW_USER_SCRIPT_INTERVAL Specifies the waiting time between two runs of the user-script. The value '0 'should only be used, if 'sleep' is executed in the script.

OW_DEVICE_LIB Specifies the absolute path and file name of the component library on the router. By using a value other than the default value '/srv/www/include/ow-device.lib' it may be ensured that the component library will not be overwritten when updating the opt library and personal changes are preserved.

OW_INVERT_PORT_LEDS Inverts the state of the port Leds of i/o ports (latch*, sensed*, PIO*).

Default setting is 'no'.

1.12. Variables Not Documented

The following variables are not (yet) documented:

OW_MODULE_CONF_FILE

OW_USER_SCRIPT_STOP

OW_SCRIPT_WRAPPER

OW_MENU_ITEM

OW_RIGHTS_SECTION

OW_OWFS_PID_FILE

OW_OWFS_GROUP_x_NAME

OW_REFRESH_FILE

OW_REFRESH_TEMP

OW_ALIAS_FILE

OW_CSS_FILE

OW_OWHTTPD_FAKE

OW_OWHTTPD_TESTER

OW_OWHTTPD_PID_FILE

1.13. Operation In Browser And Console

1.13.1. Browser

1.13.1.1. Web Server

fli4l's optionally installable web server (opt_httpd) offers the possibility to execute own shell/CGI script applications from any browser on the network. This was used here. To use the web server config/httpd.txt must be configured accordingly.

In `OPT_OW` a browser application is provided. It only will be installed, if `OW_OWFS`='yes' is set in /config/ow.txt. The script is located at /srv/www/admin/ow.cgi and under `fli4l-version\opt\files\srv\www\admin\ow.cgi` in the fli4l installation directory. The menu entry appears at „Opt / 1–Wire-Bus".

1.13.1.2. Display

Under the tab „Status" the componetens connected to the 1–wire bus are displayed grouped in a tree structure according to the settings in config/ow.txt. The group is opened by ‚clicking' on it. The values configured will be shown. In the admin structure all parameters defined for the component in the component library (see 8.4) are shown. Concerning the meaning of the parameters see the data sheets of Maxim and the referenced manpages.

Under the tab „Admin" (only shown in admin mode) the chosen applications may be switched on or off.

The LEDs shown signal the following states by colors:

- LED green = not active (Unoperational)
- LED red = active (Operational)
- LED yellow = not active (Warning)

The control buttons are used to switch the assigned ports. The icon indicates the current switching status in addition. Regarding the permissions, see 8.1.

1.13.2. Console

The query and control of sensors and actuators is also possible on the console of the fli4l or via remote access (i.e. WinSCP, Putty).

For example with:

- cat /var/run/ow/10.DEF0A8010800/temperature
  the temperature of a DS19S20 is queried.
- echo "1" > /var/run/ow/1C.7F6CF7040000/PIO.O
  output 1 of a DS28E04-100 (dual switch) is activated.
- echo "0" > /var/run/ow/1C.7F6CF7040000/PIO.O
  output 1 is deactivated again.

Further description can be found in the appendix „A.6" and here:
http://owfs.org/index.php?page=owfs

1.14. Advanced Features

1.14.1. Assignment Of Rights

The assignment of user rights is implemented in fli4l's web interface
(see the notes in doc/english/pdf/httpd.pdf).
`OPT_OW` akes use of this too. To use the OW rights the following modes can be specified in the file config/httpd.txt for the area „ow“:

- admin = all rights
- exec = execute commands, switch In- and Outputs, View data
- view = view data

The Admin tab by which owfs and the user-script may be switched on and off will not be displayed in the mode „exec“ and „view“. All entries containing an „Admin“ will be disabled too.

1.14.2. Components Library

Due to the variety of 1–wire components offered by MAXIM an own component library was created. The corresponding library script is on the fli4l in /srv/www/include/ow-device.lib and in the fli4l installation directory under `fli4l-version\opt\files\srv\www\include\ow-device.lib`. The library already contains some important components. Own devices can be added according to the nomenclature used and shared with other fli4l users on the fli4l newsgroups at 'spline.fli4l.opt'. Only components in the library will be shown in the browser. The library scripts may be edited as desired either for testing purposes or as a permanent change on the router itself using programs such as „WinSCP“ or in the fli4l installation directory.

1.14.3. OW_USER_SCRIPT

The script can be found on the router under /usr/local/bin/ow-user-script.sh and in the fli4l installation directory at `fli4l-version\opt\files\usr\local\bin\ow-userscript.sh`. It can be adapted to reflect your current needs for applications to be monitored and/or controlled. The advantage of the script is the fact that even large and complex controls are possible on existing hardware.

1.15. RRDTool

1.15.1. Interface

The data collected via the 1–Wire-Bus may be recorded and graphically presented by the fli4l-Opt „RRDTool“ This opt already contains the necessary interfaces. Owfs (see /config/ow.txt) has to be installed. When installing RRDTool configure the entries in /config/rrdtool.txt to your needs. For package OW the `OW_SHELL` has to be set to port 127.0.0.1:4304 because RRDTool's Collectd-Plugin listens on this port will display the data from all sensors in separate graphics.

1.16. Feedback

We welcome any, even short feedback, even if the package is running without any problems.

Have a lot of fun with 1–wire!

Klaus der Tiger email: der.tiger.opt-ow@arcor.de
Karl M. Weckler email: news4kmw@web.de
Roland Franke email: fli4l@franke-prem.de

A. Appendix For Package OW

A.1. Pin-Wiring For TP-Cabel and RJ-45

An overview of the wiring variants can be found here:
http://www.1wire.org/media/A_Guide_to_the_1WRJ45_Standard_Draft.zip

Who does not want to struggle through all the variants may use the following universal and sustainable scheme for the RJ45 pin assignment.

Color Specification acc. to:			
Pin	EIA/TIA 568A		EIA/TIA 568B
1	Green/White	Main Supply GND	Orange/White
2	Green	Main Supply +5V/50mA for 1–Wire Components	Orange
3	Orange/White	Secondary 1–Wire Bus GND	Green/White
4	Blue	Primary 1–Wire Bus	Blue
5	Blue/White	Primary 1–Wire Bus GND	Blue/White
6	Orange	Secondary 1–Wire Bus	Green
7	Brown/White	Auxiliary Supply i.e. +12V/200mA for other consumers	Brown/White
8	Brown	Auxiliary Supply GND	Brown

Note: For long busses the ohmic resistance has a negative effect on the supply voltages. Use an application-side power supply to prevent that.

A.2. Family Code Referenz

(From Maxim AppNote 155)

Family Code (hex)	Component / Chip	Description (Memory Size in bits, wnaa)
01	(DS1990A), (DS1990R), DS2401, DS2411	1–Wire net address (registration number) only
02	(DS1991)*	Multikey iButton, 1152-bit secure memory
04	(DS1994), DS2404	4Kb NV RAM memory and clock, timer, alarms
05	DS2405*	Single addressable switch
06	(DS1993)	4Kb NV RAM memory
08	(DS1992)	1Kb NV RAM memory
09	(DS1982), DS2502	1Kb EPROM memory
0A	(DS1995)	16Kb NV RAM memory
0B	(DS1985), DS2505	16Kb EPROM memory
0C	(DS1996)	64Kb NV RAM memory
0F	(DS1986), DS2506	64Kb EPROM memory
10	(DS1920)	Temperature with alarm trips
12	DS2406, DS2407*	1Kb EPROM memory, 2-channel addressable switch
14	(DS1971), DS2430A*	256-bit EEPROM memory and 64-bit OTP register
1A	(DS1963L)*	4Kb NV RAM memory with write cycle counters
1C	DS28E04-100	4096-bit EEPROM memory, 2-channel addressable switch
1D	DS2423*	4Kb NV RAM memory with external counters
1F	DS2409*	2-channel addressable coupler for sub-netting
20	DS2450	4-channel A/D converter (ADC)
21	(DS1921G), (DS1921H), (DS1921Z)	Thermochron® temperature logger
23	(DS1973), DS2433	4Kb EEPROM memory
24	(DS1904), DS2415	Real-time clock (RTC)
27	DS2417	RTC with interrupt
29	DS2408	8-channel addressable switch
2C	DS2890*	1-channel digital potentiometer
2D	(DS1972), DS2431	1024-bit, 1-Wire EEPROM
37	(DS1977)	Password-protected 32KB (bytes) EEPROM
3A	(DS2413)	2-channel addressable switch
41	(DS1922L), (DS1922T), (DS1923), DS2422	High-capacity Thermochron (temperature) and Hygrochron™ (humidity) loggers
42	DS28EA00	Programmable resolution digital thermometer with sequenced detection and PIO
43	DS28EC20	20Kb 1-Wire EEPROM

The list does not claim to be complete.
* These chips are no longer recommended for new designs.

A.6. Man-Pages

The complete manual pages list is available at: http://owfs.org/index.php?page=software

A.6.1. OWFS

Name **owfs** - 1-wire filesystem

Synopsis **owfs** [*-c* config] *-d* serialport | *-u* | *-s* [host:]port *-m* mountdir

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.

Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.

The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

owfs **owfs (1)** is the filesystem client of the *OWFS* family of programs. It runs on linux, freebsd and Mac OS X, and requires the *fuse* kernel module and library. (http://fuse.sourceforge.net/) which is a user-mode filesystem driver.

Essentially, the entire 1-wire bus is mounted to a place in your filesystem. All the 1-wire devices are accessible using standard file operations (read, write, directory listing). The system is safe, no actual files are exposed, these files are virtual. Not all operations are supported. Specifically, file creation, deletion, linking and renaming are not allowed. (You can link from outside to a owfs file, but not the other way around).

Device Options (1-wire Bus Master) These options specify the device (bus master) connecting the computer to the 1-wire bus. The 1-wire slaves are connected to the 1-wire bus, and the bus master connects to a port on the computer and controls the 1-wire bus. The bus master is either an actual physical device, the kernel w1 module, or an **owserver (1)**.

At least one device option is required. There is no default. More than one device can be listed, and all will be used. (A logical union unless you explore the */bus.n/* directories.)

Linux and BSD enforce a security policy restricting access to hardware ports. You must have sufficient rights to access the given port or access will silently fail.

Serial devices *port* specifies a serial port, e.g. */dev/ttyS0*

-d port | ***–device=port (DS2480B)*** DS2480B-based bus master (like the DS9097U or the LINK in emulation mode). If the adapter doesn't respond, a passive type (DS9907E or diode/resistor) circuit will be assumed.

–serial_flextime | **–serial_regulartime (DS2480B)** Changes details of bus timing (see DS2480B datasheet). Some devices, like the *Swart* LCD cannot work with *flextime.*

–baud=**1200|9600|19200|38400|57600|115200 (DS2480B,LINK,HA5)** Sets the initial serial port communication speed for all bus masters. Not all serial devices support all speeds. You can change the individual bus master speed for the **LINK** and **DS2880B** in the interface/settings directory. The **HA5** speed is set in hardware, so the command line buad rate should match that rate.

Usually the default settings (9600 for **LINK** and **DS2480B**) and 115200 for the **HA5** are sane and shouldn't be changed.

–straight_polarity | ***–reverse_polarity (DS2480B)*** Reverse polarity of the DS2480B output transistors? Not needed for the DS9097U, but required for some other designs.

–link=port (LINK) **iButtonLink** *LINK* adapter (all versions) in non-emulation mode. Uses an ascii protocol over serial.

–ha7e=port (HA7E) **Embedded Data Systems** *HA7E* adapter (and *HA7S*) in native ascii mode.

–ha5=port | ***–ha5=port:a*** | ***–ha5=port:acg (HA5)*** **Embedded Data Systems** *HA5* mutidrop adapter in native ascii mode. Up to 26 adapters can share the same port, each with an assigned letter. If no letter specified, the program will scan for the first response (which may be slow).

–checksum | **–no_checksum (HA5)** Turn on (default) or off the checksum feature of the HA5 communication.

–passive=port | ***–ha2=port*** | ***–ha3=port*** | ***–ha4b=port (Passive)*** Passive 1-wire adapters. Powered off the serial port and using passive electrical components (resitors and diodes).

–8bit | **–6bit (Passive)** Synthesize the 1-wire waveforme using a 6-bit (default) serial word, or 8-bit word. Not all UART devices support 6 bit operation.

–timeout_serial=5 Timeout (in seconds) for all serial communications. 5 second default. Can be altered dynamically under */settings/timeout/serial*

USB devices The only supported true USB bus masters are based on the DS2490 chip. The most common is the DS9490R which has an included 1-wire ID slave with family code 81.

There are also bus masters based on the serial chip with a USB to serial conversion built in. These are supported by the serial bus master protocol.

-u | ***–usb*** DS2490 based bus master (like the DS9490R).

-u2 | ***–usb=2*** Use the second USB bus master. (The order isn't predicatble, however, since the operating system does not conssitently order USB devices).

-uall | ***–usb=ALL*** Use all the USB devices.

–usb_flextime | **–usb_regulartime** Changes the details of 1-wire waveform timing for certain network configurations.

–altusb Willy Robion's alternative USB timing.

–timeout_usb=5 Timeout for USB communications. This has a 5 second default and can be changed dynamically under */settings/timeout/usb*

I2C devices I2C is 2 wire protocol used for chip-to-chip communication. The bus masters: *DS2482-100,* DS2482-101 and *DS2482-800* can specify (via pin voltages) a subset of addresses on the i2c bus. Those choices are

i2c_address

0,1,2,3 0x18,0x19,0x1A,0x1B

4,5,6,7 0x1C,0x1D,0x1E,0x1F (DS2482-800 only)

port for i2c masters have the form */dev/i2c-0,* /dev/i2c-1, ...

-d port | ***–device=port*** This simple form only permits a specific *port* and the first available *i2c_address*

–i2c=port | ***–i2c=port:i2c_address*** | ***–i2c=port:ALL*** Specific i2c *port* and the *i2c_address* is either the first, specific, or all or them. The *i2c_address* is 0,1,2,...

–i2c | ***–i2c=:*** | ***–i2c=ALL:ALL*** Search the available i2c buses for either the first, the first, or every i2c adapter.

The *DS2482-800* masters 8 1-wire buses and so will generate 8 */bus.n* entries.

Network devices These bus masters communicate via the tcp/ip network protocol and so can be located anywhere on the network. The *network_address* is of the form tcp_address:port

E.g. 192.168.0.1:3000 or localhost:3000

–link=network_address LinkHubE network LINK adapter by **iButtonLink**

–ha7net=network_address | **–ha7net** HA7Net network 1-wire adapter with specified tcp address or discovered by udp multicast. By **Embedded Data Systems**

–timeout_ha7=60 specific timeout for HA7Net communications (60 second default).

–etherweather=network_address Etherweather adapter

-s network_address | ***–server=network_address*** Location of an **owserver (1)** program that talks to the 1-wire bus. The default port is 4304.

–timeout_network=5 Timeout for network bus master communications. This has a 1 second default and can be changed dynamically under */settings/timeout/network*

Simulated devices Used for testing and development. No actual hardware is needed. Useful for separating the hardware development from the rest of the software design.

devices is a list of comma-separated 1-wire devices in the following formats. Note that a valid CRC8 code is created automatically.

10,05,21 Hexidecimal *family* codes (the DS18S20, DS2405 and DS1921 in this example).

10.12AB23431211 A more complete hexidecimal unique address. Useful when an actual hardware device should be simulated.

DS2408,DS2489 The 1-wire device name. (Full ID cannot be speciifed in this format).

–fake=devices Random address and random values for each read. The device ID is also random (unless specified).

–temperature_low=12 **–temperature_high=44** Specify the temperature limits for the *fake* adapter simulation. These should be in the same temperature scale that is specified in the command line. It is possible to change the limits dynamically for each adapter under */bus.x/interface/settings/simulated/[temperature_low|temperature_high]*

–tester=devices Predictable address and predictable values for each read. (See the website for the algorhythm).

w1 kernel module This a linux-specific option for using the operating system's access to bus masters. Root access is required and the implementation was still in progress as of owfs v2.7p12 and linux 2.6.30.

Bus masters are recognized and added dynamically. Details of the physical bus master are not accessible, bu they include USB, i2c and a number of GPIO designs on embedded boards.

Access is restrict to superuser due to the netlink broadcast protocol employed by w1. Multitasking must be configured (threads) on the compilation.

–w1 Use the linux kernel w1 virtual bus master.

–timeout_w1=10 Timeout for w1 netlink communications. This has a 10 second default and can be changed dynamically under */settings/timeout/w1*

Specific Options

-m –mountpoint=directory_path Path of a directory to mount the 1-wire file system

The mountpoint is required. There is no default.

–allow_other Shorthand for fuse mount option "-o allow_other" Allows other users to see the fuse (owfs) mount point and file system. Requires a setting in /etc/fuse.conf as well.

–fuse-opt "options" Sends options to the fuse-mount process. Options should be quoted, e.g. "-o allow_other".

Temperature Scale Options

-C –Celsius

-F –Fahrenheit

-K –Kelvin

-R –Rankine Temperature scale used for data output. Celsius is the default.
Can also be changed within the program at */settings/units/temperature_scale*

Pressure Scale Options

–mbar (default)

–atm

–mmHg

–inHg

–psi

–Pa Pressure scale used for data output. Millibar is the default.
Can also be changed within the program at */settings/units/pressure_scale*

Format Options Choose the representation of the 1-wire unique identifiers. OWFS uses these identifiers as unique directory names.

Although several display formats are selectable, all must be in *family-id-crc8* form, unlike some other programs and the labelling on iButtons, which are *crc8-id-family* form.

-f –format="f[.]i[[.]c]" Display format for the 1-wire devices. Each device has a 8byte address, consisting of:

f family code, 1 byte

i ID number, 6 bytes

c CRC checksum, 1 byte

Possible formats are *f.i* (default, 01.A1B2C3D4E5F6), *fi* fic f.ic f.i.c and *fi.c*

All formats are accepted as input, but the output will be in the specified format.

The address elements can be retrieved from a device entry in owfs by the *family,* id and crc8 properties, and as a whole with *address.* The reversed id and address can be retrieved as *r_id* and *r_address.*

Job Control Options

-r –readonly

-w –write Do we allow writing to the 1-wire bus (writing memory, setting switches, limits, PIOs)? The *write* option is available for symmetry, it's the default.

-P –pid-file "filename" Places the PID – process ID of owfs into the specified filename. Useful for startup scripts control.

–background | –foreground Whether the program releases the console and runs in the *background* after evaluating command line options. *background* is the default.

–error_print=0|1|2|3

=0 default mixed destination: stderr foreground / syslog background

=1 syslog only

=2 stderr only

=3 /dev/null (quiet mode).

–error_level=0..9

=0 default errors only

=1 connections/disconnections

=2 all high level calls

=3 data summary for each call

=4 details level

>***4*** debugging chaff

–error_level=9 produces a lot of output

Configuration File

-c file | –configuration file Name of an **owfs (5)** configuration file with more command line parameters

Help Options See also this man page and the web site http://www.owfs.org/

-h –help=[device|cache|program|job|temperature] Shows basic summary of options.

device 1-wire bus master options

cache cache and communication size and timing

program mountpoint or TCP server settings

job control and debugging options

temperature Unique ID display format and temperature scale

-V –version *Version* of this program and related libraries.

Time Options Timeouts for the bus masters were previously listed in *Device* options. Timeouts for the cache affect the time that data stays in memory. Default values are shown.

–timeout_volatile=15 Seconds until a *volatile* property expires in the cache. Volatile properties are those (like temperature) that change on their own.
Can be changed dynamically at */settings/timeout/volatile*

–timeout_stable=300 Seconds until a *stable* property expires in the cache. Stable properties are those that shouldn't change unless explicitly changed. Memory contents for example.
Can be changed dynamically at */settings/timeout/stable*

–timeout_directory=60 Seconds until a *directory* listing expires in the cache. Directory lists are the 1-wire devices found on the bus.
Can be changed dynamically at */settings/timeout/directory*

–timeout_presence=120 Seconds until the *presence* and bus location of a 1-wire device expires in the cache.
Can be changed dynamically at */settings/timeout/presence*
There are also timeouts for specific program responses:

–timeout_server=5 Seconds until the expected response from the **owserver (1)** is deemed tardy.
Can be changed dynamically at */settings/timeout/server*

–timeout_ftp=900 Seconds that an ftp session is kept alive.
Can be changed dynamically at */settings/timeout/ftp*

Example

owfs -d /dev/ttyS0 -m /mnt/1wire Bus master on serial port

owfs -F -u -m /mnt/1wire USB adapter, temperatures reported in Fahrenheit

owfs -s 10.0.1.2:4304 -m /mnt/1wire Connect to an **owserver (1)** process that was started on another machine at tcp port 4304

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.

Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.

The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

OWSHELL programs **owdir owread owwrite** and **owget** are collectively called the **owshell** programs. They allow lightweight access to an **owserver (1)** for use in command line scripts.

Unlike **owserver (1)** owhttpd (1) owftpd (1) owhttpd (1) there is not persistent connection with the 1-wire bus, no caching and no multithreading. Instead, each program connects to a running **owserver (1)** and performs a quick set of queries.

owserver (1) performs the actual 1-wire connection (to physical 1-wire busses or other **owserver** programs), performs concurrency locking, caching, and error collection.

owshell programs are intended for use in command line scripts. An alternative approach is to mount an **owfs (1)** filesystem and perform direct file lists, reads and writes.

owdir **owdir** performs a *directory* listing. With no argument, all the devices on the main 1-wire bus will be listed. Given the name of a 1-wire device, the available properties will be listed. It is the equivalent of

***ls* directory**

in the **owfs (1)** filesystem.

owread **owread** obtains for value of a 1-wire device property. e.g. 28.0080BE21AA00/temperature gives the DS18B20 temperature. It is the equivalent of

***cat* filepath**

in the **owfs (1)** filesystem.

owwrite **owwrite** performs a change of a property, changing a 1-wire device setting or writing to memory. It is the equivalent of

***echo* "value" > filepath**

in the **owfs (1)** filesystem.

owget **owget (1)** is a convenience program, combining the function of **owdir (1)** and **owread (1)** by first trying to read the argument as a directory, and if that fails as a 1-wire property.

Standard Options

–autoserver Find an *owserver* using the Service Discovery protocol. Essentially Apple's Bonjour (aka zeroconf). Only the first *owserver* will be used, and that choice is probably arbitrary.

-s [host:]port Connect via tcp (network) to an *owserver* process that is connected to a physical 1-wire bus. This allows multiple processes to share the same bus. The *owserver* process can be local or remote.

Data Options

–hex Hexidecimal mode. For reading data, each byte of character will be displayed as two characrters 0-9ABCDEF. Most useful for reading memory locations. No spaces between data.

Writing data in hexidecimal mode just means that the data should be given as one long hexidecimal string.

–start=offset Read or write memory locations starting at the offset byte rather than the beginning. An offset of 0 means the beginning (and is the default).

–size=bytes Read up to the specified number of bytes of a memory location.

Help Options

-h –help Shows basic summary of options.

-V –version *Version* of this program and related libraries.

Display Options

–dir Modify the display of directories to indicate which entries are also directories. A directory member will have a trailing '/' if it is a directory itself. This aids recursive searches.

-f –format "f[.]i[[.]c]" Display format for the 1-wire devices. Each device has a 8 byte address, consisting of:

f family code, 1 byte

i ID number, 6 bytes

c CRC checksum, 1 byte

Possible formats are *f.i* (default, 01.A1B2C3D4E5F6), *fi* fic f.ic f.i.c and *fi.c*
All formats are accepted as input, but the output will be in the specified format.

Example

owdir -s 3000 –format fic Get the device listing (full 16 hex digits, no dots) from the local *owserver* at port 3000

owread -F –autoserver 51.125499A32000/typeK/temperature Read temperature from the DS2751-based thermocouple on an auto-discovered *owserver* Temperature in fahrenheit.

owwrite -s 10.0.1.2:3001 32.000800AD23110/pages/page.1 "Passed" Connect to a OWFS server process (*owserver*) that was started on another machine at tcp port 3001 and write to the memory of a DS2780

A.6.3. OWFS.CONF

Name **owfs.conf** - owfs programs configuration file

Synopsis An OWFS configuration file is specified on the command line:

owfs -c config_file [other options] The file name is arbitrary, there is no default configuration file used.

Usage A configuration file can be invoked for any of the OWFS programs (**owfs (1)** owhttpd (1) owserver (1) owftpd (1)) or any of the language bindings (**owperl (1)** owcapi (1) owtcl (1) owphp owpython) to set command line parameters.

Syntax Similar to Unix shell script or perl syntax

Comments # Any # marks the start of a comment

blank lines are ignored

Options **option** # some options (like 'foreground') take no values

option = value # other options need a value

option value # '=' can be omitted if whitespace separates

Option # Case is ignored (for options, not values)

opt # non-ambiguous abbreviation allowed

-opt –opt # hyphens ignored

owserver **server:** opt = value # only *owserver* effected by this line

! server: opt = value # *owserver* NOT effected by this line

owhttpd **http:** opt = value # only *owhttpd* effected by this line

! http: opt = value # *owhttpd* NOT effected by this line

owftpd **ftp:** opt = value # only *owftpd* effected by this line

! ftp: opt = value # *owftpd* NOT effected by this line

owfs **owfs:** opt = value # only *owfs* effected by this line

! owfs: opt = value # *owfs* NOT effected by this line

Limits # maximum line length of 250 characters

no limit on number of lines

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.

Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.

The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

Configuration **owfs.conf (5)** allows a uniform set of command line parameters to be set.

Not all OWFS programs use the same command line options, but the non-relevant ones will be ignored.

Command line and configuration options can mixed. They will be invoked in the order presented. Left to right for the command line. Top to bottom for the configuration file.

Configuration files can call other configuration files. There is an arbitrary depth of 5 levels to prevent infinite loops. More than one configuration file can be specified.

Sample

Here is a sample configuration file with all the possible parameters included. **# Sources**

device = /dev/ttyS0 # serial port: DS9097U DS9097 ECLO or LINK

device = /dev/i2c-0 # i2c port: DS2482-100 or DS2482-800

A.6.4. DS18S20

Name DS18S20 - High-Precision 1-Wire Digital Thermometer
DS1920 - iButton version of the thermometer

Synopsis Thermometer.
10 [.]XXXXXXXXXXXX[XX][/[**die** | **power** | **temperature** | **temphigh** | **templow** | **trim** | **trimblanket** | **trimvalid** | **address** | **crc8** | **id** | **locator** | **r_address** | **r_id** | **r_locator** | **type**]]

Family Code *10*

Special Properties

power *read-only,yes-no*
Is the chip powered externally (=1) or from the parasitically from the data bus (=0)?

temperature *read-only,* floating point
Temperature read by the chip at high resolution (12 bits). Units are selected from the invoking command line. See **owfs(1)** or **owhttpd(1)** for choices. Default is Celsius. Conversion takes 1000 msec.

Temperature Alarm Limits When the device exceeds either *temphigh* or *templow* temperature threshold the device is in the alarm state, and will appear in the alarm directory. This provides an easy way to poll for temperatures that are unsafe, especially if *simultaneous* temperature conversion is done.
Units for the temperature alarms are in the same *temperature* scale that was set for *temperature* measurements.
Temperature thresholds are stored in non-volatile memory and persist until changed, even if power is lost.

temphigh *read-write,* integer
Shows or sets the lower limit for the high temperature alarm state.

templow *read-write,* integer
Shows or sets the upper limit for the low temperature alarm state.

Temperature Errata There are a group of obscure internal properties exposed to protect against an hardware defect in certain batches of the B7 die of some DS18x20 chips. See http://www.1wire.org/en-us/pg_18.html or request AN247.pdf from Dallas directly.

errata/die *read-only,ascii*
Two character manufacturing die lot. "B6" "B7" or "C2"

errata/trim *read-write,unsigned* integer

32 bit trim value in the EEPROM of the chip. When written, it does not seem to read back. Used for a production problem in the B7 *die.*

Read allowed for all chips. Only the B7 chips can be written.

errata/trimblanket *read-write,yes-no*

Writing non-zero (=1) puts a default trim value in the chip. Only applied to the B7 *die.* Reading will be true (non-zero) if trim value is the blanket value. Again, only B7 chips will register true, and since the written trim values cannot be read, this value may have little utility.

errata/trimvalid *read-only,yes-no*

Is the *trim* value in the valid range? Non-zero if true, which includes all non-B7 chips.

Standard Properties

address

r_address *read-only,* ascii

The entire 64-bit unique ID. Given as upper case hexidecimal digits (0-9A-F).

address starts with the *family* code

r address is the *address* in reverse order, which is often used in other applications and labeling.

crc8 *read-only,* ascii

The 8-bit error correction portion. Uses cyclic redundancy check. Computed from the preceding 56 bits of the unique ID number. Given as upper case hexidecimal digits (0-9A-F).

family *read-only,* ascii

The 8-bit family code. Unique to each *type* of device. Given as upper case hexidecimal digits (0-9A-F).

id

r_id *read-only,* ascii

The 48-bit middle portion of the unique ID number. Does not include the family code or CRC. Given as upper case hexidecimal digits (0-9A-F).

r id is the *id* in reverse order, which is often used in other applications and labeling.

locator

r_locator *read-only,* ascii

Uses an extension of the 1-wire design from iButtonLink company that associated 1-wire physical connections with a unique 1-wire code. If the connection is behind a **Link Locator** the *locator* will show a unique 8-byte number (16 character hexidecimal) starting with family code FE.

If no **Link Locator** is between the device and the master, the *locator* field will be all FF.

r locator is the *locator* in reverse order.

present (DEPRECATED) *read-only,* yes-no

Is the device currently *present* on the 1-wire bus?

type *read-only,* ascii

Part name assigned by Dallas Semi. E.g. *DS2401* Alternative packaging (iButton vs chip) will not be distiguished.

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.

Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.

The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

Ds18s20 Ds1920 The **DS18S20 (3)** is one of several available 1-wire temperature sensors. It has been largely replaced by the **DS18B20 (3)** and **DS1822 (3)** as well as temperature/vlotage measurements in the **DS2436 (3)** and **DS2438 (3)**. For truly versatile temperature measurements, see the protean **DS1921 (3)** Thermachron (3).

Addressing All 1-wire devices are factory assigned a unique 64-bit address. This address is of the form:

Family Code 8 bits

Address 48 bits

CRC 8 bits

Addressing under OWFS is in hexidecimal, of form:

01.123456789ABC

where **01** is an example 8-bit family code, and **12345678ABC** is an example 48 bit address. The dot is optional, and the CRC code can included. If included, it must be correct.

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.

Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.

The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

Ds2401 Ds1990a The **DS2401 (3)** and **DS1990A (3)** are the most basic of 1-wire devices. Their sole property is it's unique address. It can be used for unique identification. Nonetheless, many keylocks, night watchman systems, and tracking systems use this device.

Addressing All 1-wire devices are factory assigned a unique 64-bit address. This address is of the form:

Family Code 8 bits

Address 48 bits

CRC 8 bits

Addressing under OWFS is in hexidecimal, of form:

01.123456789ABC

where **01** is an example 8-bit family code, and **12345678ABC** is an example 48 bit address. The dot is optional, and the CRC code can included. If included, it must be correct.

A.6.6. DS2406 DS2407

Name DS2406, DS2407 - Dual Addressable Switch with 1kbit Memory

Synopsis Dual Switch, Write-once Memory
12 [.]XXXXXXXXXXXX[XX][/[**channels** | **latch.[A|B|ALL|BYTE]** | **memory** | **pages/page.[0-3|ALL]** | **PIO.[A|B|ALL|BYTE]** | **power** | **sensed.[A|B|ALL|BYTE]** | **set_alarm** | **TAI8570/[sibling|temperature|pressure]** | **T8A/volt.[0-7,ALL]** **address** | **crc8** | **id** | **locator** | **r_address** | **r_id** | **r_locator** | **type**]]

Family Code *12*

Special Properties

channels *read-only,* unsigned integer
Is this a 1 or 2 channel switch? The *DS2406* comes in two forms, one has only one *PIO* pin (PIO.A). Returns 1 or 2.

latch.A latch.B latch.ALL latch.BYTE *read-write,* yes-no

The activity latch is set to 1 with the first negative or positive edge detected on the associated PIO channel.

Writing any data will clear latch for all (both)) channels. This is a hardware "feature" of the chip.

ALL references both channels simultaneously, comma separated

BYTE references both channels simultaneously as a single byte, with channel A in bit 0.

memory *read-write,* binary

128 bytes of non-volatile, write-once data.

pages/page.0 ... pages/page.3 pages/page.ALL *read-write,* binary

Memory organized as 4 pages or 32 bytes. Memory is write-once.

ALL is the aggregate of all 4 pages, sequentially accessed.

Pio.a Pio.b Pio.all Pio.byte *read-write,* yes-no

State of the open-drain output (*PIO*) pin. 0 = non-conducting (off), 1 = conducting (on).

Writing zero will turn off the switch, non-zero will turn on the switch. Reading the *PIO* state will return the switch setting (flipflop in the data sheet). To determine the actual logic level at the switch, refer to the *sensed* property.

Note that the actual pin setting for the chip uses the opposite polarity – 0 for conducting, 1 for non-conducting. However, to turn a connected device on (i.e. to deliver power) we use the software concept of 1 as conducting or "on".

ALL references both channels simultaneously, comma separated.

BYTE references both channels simultaneously as a single byte, with channel A in bit 0.

power *read-only,* yes-no

Is the *DS2406* powered parasitically =0 or separately on the Vcc pin =1

sensed.A sensed.B sensed.ALL sensed.BYTE *read-only,* yes-no

Logic level at the *PIO* pin. 0 = ground. 1 = high (2.4V - 5V). Really makes sense only if the *PIO* state is set to zero (off), else will read zero.

ALL references both channels simultaneously, comma separated.

BYTE references both channels simultaneously as a single byte, with channel A in bit 0.

set_alarm *read-write,* unsigned integer (0-331)

A number consisting of three digits XYZ, where:

X channel selection

0 neither

1 A only

2 B only

3 A or B

Y source selection

0 undefined

1 latch

2 PIO

3 sensed

Z polarity selection

0 low

1 high

All digits will be truncated to the 0-3 (or 0-1) range. Leading zeroes are optional (and may be problematic for some shells).

Example:

311 Responds on Conditional Search when either latch.A or latch.B (or both) are set to 1.

<**100** Never responds to Conditional Search.

Tai8570/ *subdirectory*

Properties when the *DS2406* (3) is built into a *TAI8570.*

If the *DS2406* (3) is not part of a *TAI8570* or is not the controlling switch, attempts to read will result in an error.

TAI8570/pressure *read-only,* floating point

Barometric *pressure* in millibar.

TAI8570/sibling *read-only,* ascii

Hex address of the *DS2406* (3) paired with this chip in a *TAI8570.*

TAI8570/temperature *read-only,* floating-point

Ambient *temperature* measured by the *TAI8570* in prevailing temperature units (Centigrade is the default).

T8A/volt.[0-7|ALL] *read-only,* floating-point

Uses the T8A (by *Embedded* Data Systems) 8 channel voltage converter. Units in volts, 0 to 5V range. 12 bit resolution.

Standard Properties

address

r_address *read-only,* ascii

The entire 64-bit unique ID. Given as upper case hexidecimal digits (0-9A-F).

address starts with the *family* code

r address is the *address* in reverse order, which is often used in other applications and labeling.

crc8 *read-only,* ascii
The 8-bit error correction portion. Uses cyclic redundancy check. Computed from the preceding 56 bits of the unique ID number. Given as upper case hexidecimal digits (0-9A-F).

family *read-only,* ascii
The 8-bit family code. Unique to each *type* of device. Given as upper case hexidecimal digits (0-9A-F).

id

r_id *read-only,* ascii
The 48-bit middle portion of the unique ID number. Does not include the family code or CRC. Given as upper case hexidecimal digits (0-9A-F).
r id is the *id* in reverse order, which is often used in other applications and labeling.

locator

r_locator *read-only,* ascii
Uses an extension of the 1-wire design from iButtonLink company that associated 1-wire physical connections with a unique 1-wire code. If the connection is behind a **Link Locator** the *locator* will show a unique 8-byte number (16 character hexidecimal) starting with family code FE.
If no **Link Locator** is between the device and the master, the *locator* field will be all FF.
r locator is the *locator* in reverse order.

present (DEPRECATED) *read-only,* yes-no
Is the device currently *present* on the 1-wire bus?

type *read-only,* ascii
Part name assigned by Dallas Semi. E.g. *DS2401* Alternative packaging (iButton vs chip) will not be distiguished.

Alarms Use the *set_alarm* property to set the alarm triggering criteria.

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.
Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.
The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

Ds2406 The **DS2406 (3)** allows control of other devices, like LEDs and relays. It superceeds the **DS2405** and **DS2407** Alternative switches include the **DS2408** or even **DS2450**

The **DS2407** is practically identical to the *DS2406* except for a strange *hidden* mode. It is supported just like the **DS2406**

Tai8570 The *TAI-8570* Pressure Sensor is based on a 1-wire composite device by *AAG* Electronica. The *TAI8570* uses 2 *DS2406* (3) chips, paired as a reader and writer to synthesize 3-wire communication. Only 1 of the *DS2406* (3) will allow *temperature* or *pressure* readings. It's mate's address can be shown as *sibling.*

The *TAI8570* uses the *Intersema* MS5534a pressure sensor, and stores calibration and temperature compensation values internally.

Design and code examples are available from AAG Electronica http://aag.com.mx/ , specific permission to use code in a GPL product was given by Mr. Aitor Arrieta of AAG and Dr. Simon Melhuish of OWW.

Addressing All 1-wire devices are factory assigned a unique 64-bit address. This address is of the form:

Family Code 8 bits

Address 48 bits

CRC 8 bits

Addressing under OWFS is in hexidecimal, of form:

01.123456789ABC

where **01** is an example 8-bit family code, and **12345678ABC** is an example 48 bit address. The dot is optional, and the CRC code can included. If included, it must be correct.

A.6.7. DS2408

Name DS2408 - 1-Wire 8 Channel Addressable Switch

Synopsis 8 port switch
29 [.]XXXXXXXXXXXX[XX][/[**latch.[0-7|ALL|BYTE]** | **LCD_M/[clear|home|screen|message]** | **LCD_H/[clear|home|yxscreen|screen|message|onoff]** | **PIO.[0-7|ALL|BYTE]** | **power** | **sensed.[0-7|ALL|BYTE]** | **strobe** | **por** | **set_alarm** | **address** | **crc8** | **id** | **locator** | **r_address** | **r_id** | **r_locator** | **type**]]

Family Code *29*

Special Properties

latch.0 ... latch.7 latch.ALL latch.BYTE *read-write,* binary
The 8 pins (PIO) latch a bit when their state changes, either externally, or through a write to the pin.
Reading the *latch* property indicates that the latch has been set.
Writing "true" (non-zero) to ANY *latch* will reset them all. (This is the hardware design).
ALL is all *latch* states, accessed simultaneously, comma separated.
BYTE references all channels simultaneously as a single byte. Channel 0 is bit 0.

Pio.0 ... Pio.7 Pio.all Pio.byte *read-write,* yes-no
State of the open-drain output (*PIO*) pin. 0 = non-conducting (off), 1 = conducting (on).
Writing zero will turn off the switch, non-zero will turn on the switch. Reading the *PIO* state will return the switch setting. To determine the actual logic level at the switch, refer to the *sensed.0* ... sensed.7 sensed.ALL sensed.BYTE property.
ALL references all channels simultaneously, comma separated.
BYTE references all channels simultaneously as a single byte. Channel 0 is bit 0.

power *read-only,* yes-no
Is the *DS2408* powered parasitically (0) or separately on the Vcc pin (1)?

sensed.0 ... sensed.7 sensed.ALL *read-only,* yes-no
Logic level at the *PIO* pin. 0 = ground. 1 = high (2.4V - 5V). Really makes sense only if the *PIO* state is set to zero (off), else will read zero.
ALL references all channels simultaneously, comma separated.
BYTE references all channels simultaneously as a single byte. Channel 0 is bit 0.

strobe *read-write,* yes-no
RSTZ Pin Mode Control. Configures RSTZ as either RST input or STRB output:

0 configured as RST input (default)

1 configured as STRB output

por *read-write,* yes-no
Specifies whether the device has performed power-on reset. This bit can only be cleared to 0 under software control. As long as this bit is 1 the device will allways respond to a conditional search.

set_alarm *read-write,* integer unsigned (0-333333333)
A number consisting of 9 digits XYYYYYYYY, where:

X select source and logical term

0 PIO OR

1 latch OR

2 PIO AND

3 latch AND

Y select channel and polarity

0 Unselected (LOW)

1 Unselected (HIGH)

2 Selected LOW

3 Selected HIGH

All digits will be truncated to the 0-3 range. Leading zeroes are optional. Low-order digit is channel 0.
Example:

100000033 Responds on Conditional Search when latch.1 or latch.0 are set to 1.

222000000 Responds on Conditional Search when sensed.7 and sensed.6 are set to 0.

000000000 (0) Never responds to Conditional Search.

Lcd_h Lcd Screen Properites This mode uses the *DS2408* attached to a Hitachi HD44780 LCD controller in 4-bit mode. See *DATASHEET* for published details. Based on a commercial product from *HobbyBoards* by Erik Vickery.

LCD_H/clear *write-only,* yes-no
This will *clear* the screen and place the cursor at the start.

LCD_H/home *write-only,* yes-no
Positions the cursor in the *home* (upper left) position, but leaves the current text intact.

LCD_H/screen *write-only,* ascii text
Writes to the LCD *screen* at the current position.

LCD_H/screenyc *write-only,* ascii text
Writes to an LCD screen at a specified location. The controller doesn't know the true LCD dimensions, but typical selections are: 2x16 2x20 4x16 and 4x20.

Y (row) range 1 to 2 (or 4)

X (column) range 1 to 16 (or 20)

There are two formats allowed for the *screenyx* text, either ascii (readable text) or a binary form.

2 binary bytes The two first characters of the passed string have the line and row: e.g. "\x02\x04string" perl string writes "string" at line 2 column 4.

ascii 2,12: Two numbers giving line and row: Separate with a comma and end with a colon e.g. "2,4:string" writes "string" at line 2 column 4.

ascii 12: Single column number on the (default) first line: End with a colon e.g. "12:string" writes "string" at line 1 column 12.

The positions are 1-based (i.e. the first position is 1,1).

LCD_H/onoff *write-only,* unsigned
Sets several screen display functions. The selected choices should be added together.

4 Display on

2 Cursor on

1 Cursor blinking

LCD_H/message *write-only,* ascii text
Writes a *message* to the LCD screen after clearing the screen first. This is the easiest way to display a message.

Lcd_m Lcd Screen Properites This mode uses the *DS2408* attached to a Hitachi HD44780 LCD controller in 8-bit mode. See *DATASHEET* for published details. Based on a design from Maxim and a commercial product from *AAG.*

LCD_M/clear *write-only,* yes-no
This will *clear* the screen and place the cursor at the start.

LCD_M/home *write-only,* yes-no
Positions the cursor in the *home* (upper left) position, but leaves the current text intact.

LCD_M/screen *write-only,* ascii text
Writes to the LCD *screen* at the current position.

LCD_M/screenyc *write-only,* ascii text
Writes to an LCD screen at a specified location. The controller doesn't know the true LCD dimensions, but typical selections are: 2x16 2x20 4x16 and 4x20.

Y (row) range 1 to 2 (or 4)

X (column) range 1 to 16 (or 20)

There are two formats allowed for the *screenyx* text, either ascii (readable text) or a binary form.

2 binary bytes The two first characters of the passed string have the line and row: e.g. "\x02\x04string" perl string writes "string" at line 2 column 4.

ascii 2,12: Two numbers giving line and row: Separate with a comma and end with a colon e.g. "2,4:string" writes "string" at line 2 column 4.

ascii 12: Single column number on the (default) first line: End with a colon e.g. "12:string" writes "string" at line 1 column 12.

The positions are 1-based (i.e. the first position is 1,1).

LCD_M/onoff *write-only,* unsigned
Sets several screen display functions. The selected choices should be added together.

4 Display on

2 Cursor on

1 Cursor blinking

LCD_M/message *write-only,* ascii text
Writes a *message* to the LCD screen after clearing the screen first. This is the easiest way to display a message.

Standard Properties

address

r_address *read-only,* ascii
The entire 64-bit unique ID. Given as upper case hexidecimal digits (0-9A-F).
address starts with the *family* code
r address is the *address* in reverse order, which is often used in other applications and labeling.

crc8 *read-only,* ascii
The 8-bit error correction portion. Uses cyclic redundancy check. Computed from the preceding 56 bits of the unique ID number. Given as upper case hexidecimal digits (0-9A-F).

family *read-only,* ascii
The 8-bit family code. Unique to each *type* of device. Given as upper case hexidecimal digits (0-9A-F).

id

r_id *read-only,* ascii
The 48-bit middle portion of the unique ID number. Does not include the family code or CRC. Given as upper case hexidecimal digits (0-9A-F).
r id is the *id* in reverse order, which is often used in other applications and labeling.

locator

r_locator *read-only,* ascii
Uses an extension of the 1-wire design from iButtonLink company that associated 1-wire physical connections with a unique 1-wire code. If the connection is behind a **Link Locator** the *locator* will show a unique 8-byte number (16 character hexidecimal) starting with family code FE.
If no **Link Locator** is between the device and the master, the *locator* field will be all FF.
r locator is the *locator* in reverse order.

present (DEPRECATED) *read-only,* yes-no
Is the device currently *present* on the 1-wire bus?

type *read-only,* ascii
Part name assigned by Dallas Semi. E.g. *DS2401* Alternative packaging (iButton vs chip) will not be distiguished.

Alarms Use the *set_alarm* property to set the alarm triggering criteria.

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.
Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.
The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.
Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

Ds2408 The **DS2408 (3)** allows control of other devices, like LEDs and relays. It extends the **DS2406** to 8 channels and includes memory.

Alternative switches include the **DS2406, DS2407** and even **DS2450**

Addressing All 1-wire devices are factory assigned a unique 64-bit address. This address is of the form:

Family Code 8 bits

Address 48 bits

CRC 8 bits

Addressing under OWFS is in hexidecimal, of form:

01.123456789ABC

where **01** is an example 8-bit family code, and **12345678ABC** is an example 48 bit address. The dot is optional, and the CRC code can included. If included, it must be correct.

Alarms Use the *set_alarm* property to set the alarm triggering criteria.

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.

Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.

The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

Ds2413 The **DS2413 (3)** allows control of other devices, like LEDs and relays. It differs from the *DS2405* with a cleaner interface and two channels The *DS2413* also has two channels like the *DS2406* and *DS2407* but has no memory, and no alarm. There is also varying types of switch and sensing in the *DS2408,* DS2409, LCD, DS276x, DS2450.

Unique among the switches, the *DS2413* can switch higher voltages, up to 28V.

Addressing All 1-wire devices are factory assigned a unique 64-bit address. This address is of the form:

Family Code 8 bits

Address 48 bits

CRC 8 bits

Addressing under OWFS is in hexidecimal, of form:

01.123456789ABC

where **01** is an example 8-bit family code, and **12345678ABC** is an example 48 bit address. The dot is optional, and the CRC code can included. If included, it must be correct.

Author Paul Alfille (email: paul.alfille@gmail.com)

A.6.9. DS2423

Name DS2423 - 4kbit 1-Wire RAM with Counter

Synopsis RAM and counters.
1D [.]XXXXXXXXXXXX[XX][/[**counters.[A|B|ALL]** | **memory** | **pages/page.[0-15|ALL]** | **pages/count.[0-15|ALL]** | **address** | **crc8** | **id** | **locator** | **r_address** | **r_id** | **r_locator** | **type**]]

Family Code *1D*

Special Properties

counters.A counters.B counters.ALL *read-only,* unsigned integer
Debounced external counter. Associated with RAM *page.14* and *page.15* Note: counter increments only. It is reset when the chip loses power.
ALL returns the two values, separated by a comma. They are read sequentially.

memory *read-write,* binary
512 bytes of memory.

pages/page.0 ... pages/page.15 pages/page.ALL *read-write,* binary
Memory is split into 16 pages of 32 bytes each. Memory is RAM, contents are lost when power is lost. *ALL* is an aggregate of the pages. Each page is accessed sequentially.

pages/count.0 ... pages/count.15 pages/count.ALL *read-only,* unsigned integer

Write access to each page of memory. Actually only *page.12* and *page.13* have write counters.

page14 and *page.15* 's counters are associated with the external *counters.A* and *counters.B* triggers.

The value 0xFFFFFFFF is returned for *pages/count.0* through *pages/count.11*

ALL is an aggregate of the counters, comma separated. Each page is accessed sequentially.

Standard Properties

address

r_address *read-only,* ascii

The entire 64-bit unique ID. Given as upper case hexidecimal digits (0-9A-F).

address starts with the *family* code

r address is the *address* in reverse order, which is often used in other applications and labeling.

crc8 *read-only,* ascii

The 8-bit error correction portion. Uses cyclic redundancy check. Computed from the preceding 56 bits of the unique ID number. Given as upper case hexidecimal digits (0-9A-F).

family *read-only,* ascii

The 8-bit family code. Unique to each *type* of device. Given as upper case hexidecimal digits (0-9A-F).

id

r_id *read-only,* ascii

The 48-bit middle portion of the unique ID number. Does not include the family code or CRC. Given as upper case hexidecimal digits (0-9A-F).

r id is the *id* in reverse order, which is often used in other applications and labeling.

locator

r_locator *read-only,* ascii

Uses an extension of the 1-wire design from iButtonLink company that associated 1-wire physical connections with a unique 1-wire code. If the connection is behind a **Link Locator** the *locator* will show a unique 8-byte number (16 character hexidecimal) starting with family code FE.

If no **Link Locator** is between the device and the master, the *locator* field will be all FF.

r locator is the *locator* in reverse order.

present (DEPRECATED) *read-only,* yes-no

Is the device currently *present* on the 1-wire bus?

type *read-only,* ascii

Part name assigned by Dallas Semi. E.g. *DS2401* Alternative packaging (iButton vs chip) will not be distiguished.

Alarms None.

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.

Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.

The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

Ds2423 The **DS2423 (3)** is used for its counters. The internal counters (associated with pages 12 and 13) can detect memory tampering.

The external counters A and B page been used in circuit design, such as a wind anometer. *OWFS* system handles this automatically.

Addressing All 1-wire devices are factory assigned a unique 64-bit address. This address is of the form:

Family Code 8 bits

Address 48 bits

CRC 8 bits

Addressing under OWFS is in hexidecimal, of form:

01.123456789ABC

where **01** is an example 8-bit family code, and **12345678ABC** is an example 48 bit address. The dot is optional, and the CRC code can included. If included, it must be correct.

20 [.]XXXXXXXXXXXX[XX][/[**address** | **crc8** | **id** | **locator** | **r_address** | **r_id** | **r_locator** | **type**]]

CO2 sensor **20** [.]XXXXXXXXXXXX[XX][/[**CO2/ppm** | **CO2/power** | **CO2/status**]

Family Code *20*

Special Properties

alarm/high.A ... alarm/high.D alarm.high.ALL

alarm/high.A ... alarm/high.D alarm.high.ALL *read-write,* binary
The alarm state of the voltage channel. The alarm state is set one of two ways:

voltage conversion Whenever the *DS2450* measures a voltage on a channel, that voltage is compared to the high and low limits *set_alarm/volthigh* and/or *set_alarm/voltlow* and if the alarm is enabled *set_alarm/high* and/or *set_alarm/low* the corresponding flag is set in *alarm/high* and/or *alarm/low*

manual set The flag can be set by a direct write to *alarm/high* or *alarm/low*

memory *read-write,* binary
32 bytes of data. Much has special implications. See the datasheet.

pages/page.0 ... pages/page.3 pages/page.ALL *read-write,* binary
Memory is split into 4 pages of 8 bytes each. Mostly for reading and setting device properties. See the datasheet for details.
ALL is an aggregate of the pages. Each page is accessed sequentially.

Pio.a ... Pio.d Pio.all *read-write,* yes-no
Pins used for digital control. 1 turns the switch on (conducting). 0 turns the switch off (non-conducting).
Control is specifically enabled. Reading *volt* will turn off this control.
ALL is an aggregate of the voltages. Readings are made separately.

power *read-write,* yes-no
Is the *DS2450* externally powered? (As opposed to parasitically powered from the data line).
The analog A/D will be kept on continuously. And the bus will be released during a conversion allowing other devices to communicate.
Set true (1) only if Vcc powered (not parasitically powered). Unfortunately, the *DS2450* cannot sense it's powered state. This flag must be explicitly written, and thus is a potential source of error if incorrectly set.
It is always safe to leave *power* set to the default 0 (off) state.

set_alarm/high.A ... set_alarm/high.D set_alarm/high.ALL

set_alarm/low.A ... set_alarm/low.D set_alarm/low.ALL *read-write,* yes-no
Enabled status of the voltage threshold. 1 is on. 0 is off.

set_alarm/volthigh.A ... set_alarm/volthigh.D set_alarm/volthigh.ALL

set_alarm/volt2high.A ... set_alarm/volt2high.D set_alarm/volt2high.ALL

set_alarm/voltlow.A ... set_alarm/voltlow.D set_alarm/voltlow.ALL

set_alarm/volt2low.A ... set_alarm/volt2low.D set_alarm/volt2low.ALL *read-write,* floating point

The upper or lower limit for the voltage measured before triggering an alarm.

Note that the alarm must be enabled *alarm/high* or *alarm.low* and an actual reading must be requested *volt* for the alarm state to actually be set. The alarm state can be sensed at *alarm/high* and *alarm/low*

set_alarm/unset *read-write,* yes-no

Status of the power-on-reset (POR) flag.

The POR is set when the *DS2450* is first powered up, and will match the alarm state until explicitly cleared. (By writing 0 to it).

The purpose of the POR is to alert the user that the chip is not yet fully configured, especially alarm thresholds and enabling.

volt.A ... volt.D volt.ALL

8bit/volt.A ... 8bit/volt.D 8bit/volt.ALL *read-only,* floating point

Voltage read, 16 bit resolution (or 8 bit for the *8bit* directory). Range 0 - 5.10V.

Output (*PIO*) is specifically disabled.

ALL is an aggregate of the voltages. Readings are made separately.

volt2.A ... volt2.D volt2.ALL

8bit/volt2.A ... 8bit/volt2.D 8bit/volt2.ALL *read-only,* floating point

Voltage read, 16 bit resolution (or 8 bit for the *8bit* directory). Range 0 - 2.55V.

Output (*PIO*) is specifically disabled.

ALL is an aggregate of the voltages. Readings are made separately.

CO2 (Carbon Dioxide) SENSOR PROPERTIES The CO2 sensor is a device constructed from a SenseAir K30 and a *DS2450*

CO2/power *read-only,* floating point

Supply voltage to the CO2 sensor (should be around 5V)

CO2/ppm *read-only,* unsigned

CO2 level in ppm (parts per million). Range 0-5000.

CO2/status *read-only,* yes-no

Is the internal voltage correct (around 3.2V)?

Standard Properties

address

r_address *read-only,* ascii

The entire 64-bit unique ID. Given as upper case hexidecimal digits (0-9A-F).

address starts with the *family* code

r address is the *address* in reverse order, which is often used in other applications and labeling.

crc8 *read-only,* ascii

The 8-bit error correction portion. Uses cyclic redundancy check. Computed from the preceding 56 bits of the unique ID number. Given as upper case hexidecimal digits (0-9A-F).

family *read-only,* ascii

The 8-bit family code. Unique to each *type* of device. Given as upper case hexidecimal digits (0-9A-F).

id

r_id *read-only,* ascii

The 48-bit middle portion of the unique ID number. Does not include the family code or CRC. Given as upper case hexidecimal digits (0-9A-F).

r id is the *id* in reverse order, which is often used in other applications and labeling.

locator

r_locator *read-only,* ascii

Uses an extension of the 1-wire design from iButtonLink company that associated 1-wire physical connections with a unique 1-wire code. If the connection is behind a **Link Locator** the *locator* will show a unique 8-byte number (16 character hexidecimal) starting with family code FE.

If no **Link Locator** is between the device and the master, the *locator* field will be all FF.

r locator is the *locator* in reverse order.

present (DEPRECATED) *read-only,* yes-no

Is the device currently *present* on the 1-wire bus?

type *read-only,* ascii

Part name assigned by Dallas Semi. E.g. *DS2401* Alternative packaging (iButton vs chip) will not be distiguished.

Alarms None.

Description

1-Wire *1-wire* is a wiring protocol and series of devices designed and manufactured by Dallas Semiconductor, Inc. The bus is a low-power low-speed low-connector scheme where the data line can also provide power.

Each device is uniquely and unalterably numbered during manufacture. There are a wide variety of devices, including memory, sensors (humidity, temperature, voltage, contact, current), switches, timers and data loggers. More complex devices (like thermocouple sensors) can be built with these basic devices. There are also 1-wire devices that have encryption included.

The 1-wire scheme uses a single *bus* master and multiple *slaves* on the same wire. The bus master initiates all communication. The slaves can be individually discovered and addressed using their unique ID.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

Ds2450 The **DS2450 (3)** is a (supposedly) high resolution A/D converter with 4 channels. Actual resolutin is reporterd to be 8 bits. The channels can also function as switches. Voltage sensing (with temperature and current, but sometimes restricted voltrage ranges) can also be obtained with the **DS2436** , **DS2438** and **DS276x**

Addressing All 1-wire devices are factory assigned a unique 64-bit address. This address is of the form:

Family Code 8 bits

Address 48 bits

CRC 8 bits

Addressing under OWFS is in hexidecimal, of form:

01.123456789ABC

where **01** is an example 8-bit family code, and **12345678ABC** is an example 48 bit address. The dot is optional, and the CRC code can included. If included, it must be correct.

Bus masters come in a variety of configurations including serial, parallel, i2c, network or USB adapters.

OWFS design *OWFS* is a suite of programs that designed to make the 1-wire bus and its devices easily accessible. The underlying priciple is to create a virtual filesystem, with the unique ID being the directory, and the individual properties of the device are represented as simple files that can be read and written.

Details of the individual slave or master design are hidden behind a consistent interface. The goal is to provide an easy set of tools for a software designer to create monitoring or control applications. There are some performance enhancements in the implementation, including data caching, parallel access to bus masters, and aggregation of device communication. Still the fundemental goal has been ease of use, flexibility and correctness rather than speed.

Ds28ec20 The **DS28EC20 (3)** is used for storing memory which should be available even after a reset or power off. It's main advantage is for audit trails (i.e. a digital purse). *OWFS* system handles this automatically.

Addressing All 1-wire devices are factory assigned a unique 64-bit address. This address is of the form:

Family Code 8 bits

Address 48 bits

CRC 8 bits

Addressing under OWFS is in hexidecimal, of form:

01.123456789ABC

where **01** is an example 8-bit family code, and **12345678ABC** is an example 48 bit address. The dot is optional, and the CRC code can included. If included, it must be correct.
