1 Overview of GEO

The NCBI Gene Expression Omnibus (GEO) serves as a public repository for a wide range of high-throughput experimental data. These data include single and dual channel microarray-based experiments measuring mRNA, genomic DNA, and protein abundance, as well as

*sdavis2@mail.nih.gov

non-array techniques such as serial analysis of gene expression (SAGE), and mass spectrometry proteomic data. Currently, 65,000 samples and nearly 2000 different platforms are represented in GEO!

At the most basic level of organization of GEO, there are four basic entity types. The first three (Sample, Platform, and Series) are supplied by users; the fourth, the dataset, is compiled and curated by GEO staff from the user-submitted data.[1]

1.1 Platforms

A Platform record describes the list of elements on the array (e.g., cDNAs, oligonucleotide probesets, ORFs, antibodies) or the list of elements that may be detected and quantified in that experiment (e.g., SAGE tags, peptides). Each Platform record is assigned a unique and stable GEO accession number (GPLxxx). A Platform may reference many Samples that have been submitted by multiple submitters.

1.2 Samples

A Sample record describes the conditions under which an individual Sample was handled, the manipulations it underwent, and the abundance measurement of each element derived from it. Each Sample record is assigned a unique and stable GEO accession number (GSMxxx). A Sample entity must reference only one Platform and may be included in multiple Series.

1.3 Series

A Series record defines a set of related Samples considered to be part of a group, how the Samples are related, and if and how they are ordered. A Series provides a focal point and description of the experiment as a whole. Series records may also contain tables describing extracted data, summary conclusions, or analyses. Each Series record is assigned a unique and stable GEO accession number (GSExxx).

1.4 Datasets

GEO DataSets (GDSxxx) are curated sets of GEO Sample data. A GDS record represents a collection of biologically and statistically comparable GEO Samples and forms the basis of GEO's suite of data display and analysis tools. Samples within a GDS refer to the same Platform, that is, they share a common set of probe elements. Value measurements for each Sample within a GDS are assumed to be calculated in an equivalent manner, that is, considerations such as background processing and normalization are consistent across the dataset. Information reflecting experimental design is provided through GDS subsets.

[1] See `http://www.ncbi.nih.gov/geo` for more information

2 Getting Started using GEOquery

Getting data from GEO is really quite easy. There is only one command that is needed, `getGEO`. This one function interprets its input to determine how to get the data from GEO and then parse the data into useful R data structures. Usage is quite simple:

```
> library(GEOquery)
```

This loads the GEOquery library.

```
> gds <- getGEO("GDS1")
```

```
File stored at:
D:\biocbld\1.9d\tmpdir\Rtmpsy4Eqb/GDS1.soft.gz
parsing geodata
parsing subsets
ready to return
```

Now, `gds` contains the R data structure (of class *GDS*) that represents the GDS1 entry from GEO. You'll note that the filename used to store the download was output to the screen (but not saved anywhere) for later use to a call to getGEO(filename=...).

We can do the same with any other GEO accession, such as GSM3, a GEO sample.

```
> gsm <- getGEO("GSM3")
```

```
File stored at:
D:\biocbld\1.9d\tmpdir\Rtmpsy4Eqb/GSM3.soft
```

3 GEOquery Data Structures

The GEOquery data structures really come in two forms. The first, comprising *GDS*, *GPL*, and *GSM* all behave similarly and accessors have similar effects on each. The fourth GEOquery data structure, *GSE* is a composite data type made up of a combination of *GSM* and *GPL* objects. I will explain the first three together first.

3.1 The GDS, GSM, and GPL classes

Each of these classes is comprised of a metadata header (taken nearly verbatim from the SOFT format header) and a GEODataTable. The GEODataTable has two simple parts, a Columns part which describes the column headers on the Table part. There is also a *show* method for each class. For example, using the gsm from above:

```
> Meta(gsm)
```

```

```
> Columns(gsm)
```

```
      Column                                                 Description
1     ID_REF
2 SIGNAL_RAW                                                  raw signal
3   BKD_FORM
4  NORM_FORM
5    BKD_RAW raw background as taken in four quarters of microarray
6 NORM_VALUE                                       normalization value
7      CONST                                            constant value
8      VALUE
```

The *GPL* behaves exactly as the *GSM* class. However, the GDS has a bit more information associated with the *Columns* method:

```
> Columns(gds)
```

```
  sample gender                tissue
1   GSM3   male                testis
2   GSM4   male                testis
3   GSM5   male   gonadectomized male
4   GSM6   male   gonadectomized male
5   GSM7 female                 ovary
6   GSM8 female                 ovary
7   GSM9 female gonadectomized female
8  GSM10 female gonadectomized female
                                      description
1 Value for GSM3: testis a; src: y w[67c1]/Y testis
2 Value for GSM4: testis b; src: y w[67c1]/Y testis
3     Value for GSM5: male a; src: y w[67c1]/Y male
4          Value for GSM6: male b; src: y w[67c1]/Y
5     Value for GSM7: ovary a; src: y w[67c1] ovary
6     Value for GSM8: ovary b; src: y w[67c1] ovary
7   Value for GSM9: female a; src: y w[67c1] female
8  Value for GSM10: female b; src: y w[67c1] female
```

3.2 The GSE class

The *GSE* is the most confusing of the GEO entities. A GSE entry can represent an arbitrary number of samples run on an arbitrary number of platforms. The *GSE* has a metadata section, just like the other classes. However, it doesn't have a GEODataTable. Instead, it

contains two lists, accessible using *GPLList* and GSMList, that are each lists of *GPL* and *GSM* objects. To show an example:

```
> gse <- getGEO("GSE462")

File stored at:
D:\biocbld\1.9d\tmpdir\Rtmpsy4Eqb/GSE462.soft.gz
Parsing....
^PLATFORM = GPL5
^SAMPLE = GSM3
^SAMPLE = GSM4
^SAMPLE = GSM5
^SAMPLE = GSM6
^SAMPLE = GSM7

4 Converting to BioConductor exprSets and limma MALists

GEO datasets are (unlike some of the other GEO entities), quite similar to the *limma* data structure *MAList* and to the *Biobase* data structure *exprSet*. Therefore, there are two functions, `GDS2MA` and `GDS2eSet` that accomplish that task.

4.1 Converting GDS to an exprSet

Taking our `gds` object from above, we can simply do:

```
> eset <- GDS2eSet(gds, do.log2 = TRUE)
```

Now, `eset` is an *exprSet* that contains the same information as in the GEO dataset, including the sample information, which we can see here:

```
> eset

Expression Set (exprSet) with
        3456 genes
        8 samples
        phenoData object with 4 variables and 8 cases
        varLabels
                : sample
                : gender
                : tissue
                : description

> pData(eset)

      sample gender                tissue
GSM3    GSM3   male                testis
GSM4    GSM4   male                testis
GSM5    GSM5   male   gonadectomized male
GSM6    GSM6   male   gonadectomized male
GSM7    GSM7 female                 ovary
GSM8    GSM8 female                 ovary
GSM9    GSM9 female gonadectomized female
GSM10  GSM10 female gonadectomized female
                                            description
GSM3  Value for GSM3: testis a; src: y w[67c1]/Y testis
GSM4  Value for GSM4: testis b; src: y w[67c1]/Y testis
GSM5      Value for GSM5: male a; src: y w[67c1]/Y male
```

```
GSM6           Value for GSM6: male b; src: y w[67c1]/Y
GSM7      Value for GSM7: ovary a; src: y w[67c1] ovary
GSM8      Value for GSM8: ovary b; src: y w[67c1] ovary
GSM9    Value for GSM9: female a; src: y w[67c1] female
GSM10  Value for GSM10: female b; src: y w[67c1] female
```

4.2 Converting GDS to an MAList

No annotation information (called platform information by GEO) was retrieved from because *exprSet* does not contain slots for gene information, typically. However, it is easy to obtain this information. First, we need to know what platform this GDS used. Then, another call to `getGEO` will get us what we need.

```
> Meta(gds)$platform

[1] "GPL5"

> gpl <- getGEO("GPL5")

File stored at:
D:\biocbld\1.9d\tmpdir\Rtmpsy4Eqb/GPL5.soft
```

So, `gpl` now contains the information for GPL5 from GEO. Unlike *exprSet*, the limma *MAList* does store gene annotation information, so we can use our newly created `gpl` of class *GPL* in a call to `GDS2MA` like so:

```
> MA <- GDS2MA(gds, GPL = gpl)
> MA

An object of class "MAList"
$M

Now, `MA` is of class *MAList* and contains not only the data, but the sample information and gene information associated with GDS1.

4.3 Converting GSE to an exprSet

Converting a *GSE* object to an *exprSet* object currently takes a bit of R data manipulation due to the varied data that can be stored in a *GSE* and the underlying *GSM* and *GPL* objects. However, using a simple example will hopefully be illustrative of the technique.

First, we need to make sure that all of the *GSMs* are from the same platform:

```
> gsmplatforms <- lapply(GSMList(gse), function(x) {
+     Meta(x)$platform
+ })
> gsmplatforms

$GSM10
[1] "GPL5"

$GSM3
[1] "GPL5"

$GSM4
[1] "GPL5"

$GSM5
[1] "GPL5"

$GSM6
[1] "GPL5"

$GSM7
[1] "GPL5"

$GSM8
[1] "GPL5"
```

```
$GSM9
[1] "GPL5"
```

Indeed, they all used GPL5 as their platform (which we could have determined by looking at the GPLList for `gse`, which shows only one GPL for this particular GSE.). So, now we would like to know what column represents the data that we would like to extract. Looking at the first few rows of the Table of a single GSM will likely give us an idea (and by the way, GEO uses a convention that the column that contains the single "measurement" for each array is called the "VALUE" column, which we could use if we don't know what other column is most relevant).

```
> Table(GSMList(gse)[[1]])[1:5, ]
```

```
  ID_REF SIGNAL_RAW BKD_FORM NORM_FORM  BKD_RAW NORM_VALUE CONST    VALUE
1      1    4486.49        0         0 3379.579   23337.54 39542 55845.45
2      2    3482.51        0         0 3379.579   23337.54 39542 41058.05
3      3    3812.39        0         0 3379.579   23337.54 39542 45916.78
4      4    3257.56        1         0 3379.579   23337.54 39542 37744.81
5      5    5436.91        0         0 3379.579   23337.54 39542 69843.97
```

```
> Columns(GSMList(gse)[[1]])[1:5, ]
```

```
      Column    Description
1     ID_REF
2 SIGNAL_RAW     raw signal
3   BKD_FORM
4  NORM_FORM
5    BKD_RAW raw background
```

We will indeed use the "VALUE" column. We then want to make a matrix of these values like so:

```
> probesets <- Table(GPLList(gse)[[1]])$ID
> data.matrix <- log2(do.call("cbind", lapply(GSMList(gse), function(x) {
+     tab <- Table(x)
+     mymatch <- match(probesets, tab$ID_REF)
+     return(tab$VALUE[mymatch])
+ })))
> data.matrix[1:5, ]
```

```
        GSM10     GSM3     GSM4     GSM5     GSM6     GSM7     GSM8     GSM9
[1,] 15.76915 16.22921 16.13000 15.65034 17.09214 15.45853 16.09474 15.23515
[2,] 15.32538 15.26597      NaN 15.20406 16.47596 14.85776 15.14885 14.89007
[3,] 15.48673 15.80932 14.16259 15.18048 16.21235 15.06094 15.38242 14.96986
[4,] 15.20399 15.50663 13.41582 15.05939 16.18593 14.79861 14.80460 15.01923
[5,] 16.09185 17.82246 18.38270 16.24570 16.60964 15.90011 16.00962 15.88859
```

Note that we do a "match" to make sure that the values and the platform information are in the same order. Finally, to make the *exprSet* object:

```
> require(Biobase)

[1] TRUE

> rownames(data.matrix) <- probesets
> colnames(data.matrix) <- names(GSMList(gse))
> pdata <- data.frame(samples = names(GSMList(gse)))
> rownames(pdata) <- names(GSMList(gse))
> pheno <- new("phenoData", pData = pdata, varLabels = as.list("samples"))
> eset2 <- new("exprSet", exprs = data.matrix, phenoData = pheno)
> eset2

Expression Set (exprSet) with
        3456 genes
        8 samples
        phenoData object with 1 variables and 8 cases
        varLabels
                : samples
```

So, using a combination of `lapply` on the GSMList, one can extract as many columns of interest as necessary to build the data structure of choice. Because the GSM data from the GEO website are fully downloaded and included in the *GSE* object, one can extract foreground and background as well as quality for two-channel arrays, for example. Getting array annotation is also a bit more complicated, but by replacing "platform" in the lapply call to get platform information for each array, one can get other information associated with each array. Future work with this package will likely focus on better tools for manipulating *GSE* data.

5 Conclusion

The GEOquery package provides a bridge to the vast array resources contained in the NCBI GEO repositories. By maintaining the full richness of the GEO data rather than focusing on getting only the "numbers", it is possible to integrate GEO data into current Bioconductor data structures and to perform analyses on that data quite quickly and easily. These tools will hopefully open GEO data more fully to the array community at large.
